License: Synchronization of nonlinear oscillators: Phase-lock on the slippery slope?

Synchronization is a widespread phenomenon present in many physical systems. One of the most impressive types of nonlinear oscillators is the Hodgkin-Huxley model, which has in particular been used to investigate the synchronization of electrotonic nets in the nerve fibers. In this paper, we investigate synchronization

phenomena using a mathematical model describing the interaction between two neurons belonging to the same electrotonic network. The coupling is supposed to be nonlocal and to take into account various mechanisms such as action potentials, spike-frequency adaptation, and spike-timing dependent plasticity. We first show how synchronization can be established, starting from two perfectly coupled

nonoscillators. We study the conditions under which the system will automatically phase-lock as a result of intrinsic oscillations in the two neurons. We find that the stability conditions for synchronization are rather different when the coupling is of the local type, in which case the two neurons are sensitive to perturbations of each other, and when the coupling is of the nonlocal type, in which case the system becomes insensitive to perturbations of

either one of the neurons. We then study the dynamics of the system when one neuron is progressively removed from the interaction network, while the other neuron keeps its links to its neighbors. The corresponding equilibrium states depend strongly on the type of coupling involved. We finally extend our analysis to other types of nonlocal coupling and to the case of oscillators with different natural frequencies, showing that the phenomenon of

synchronization is much more
robust than initially thought.
