Mesothelioma Information Mesothelioma is a cancer of the protective lining (mesothelium) that covers the lungs (pleura), heart (pericardium), and abdominal (peritoneum) and pelvic (parietal) cavities (pleura, peritoneum, and pericardium). Occupational exposure to asbestos was most frequently associated with the development of malignant mesothelioma; exposure to asbestos by nonoccupational sources, such as via mining and handling of industrial products, and household cleaning products and textiles, has been increasing. Mesothelioma may also develop as a result of contact with, or near a person who has developed the disease, particularly when the disease is later diagnosed. A California bill (AB 1757) was passed in 2016 which requires the California DPH to develop guidelines to advise medical professionals about the risk of mesothelioma from exposure to any chemical that is a by-product of the manufacturing, mining, handling or use of a naturally occurring mineral, including asbestos. One of the most common methods for diagnosis of mesothelioma is thoracoscopy, a surgical procedure that uses a small camera and small tools to remove the cancer for examination under a microscope. This method is only used at certain cancer centers and is more expensive than CT scanning. CT imaging is a routine test for evaluation of mesothelioma. Survival of mesothelioma is poor. The median survival from diagnosis was 9 months for a person diagnosed with pleural mesothelioma.
