A gas-permeable membrane for membrane bioreactors. The present study evaluated the performance of two types of membranes, hollow fiber and flat sheet, for the filtration of aqueous streams in a membrane bioreactor. The membrane fluxes were measured using standard membrane-filtration tests and the filtration of a synthetic and a real wastewater. The fluxes, even at high gas pressure (up to 110 bar) were very low. The poor permeability is correlated to the poor selectivity towards organic substances, and it is mainly dependent on the gas pressure and the channel size in the case of flat sheet membranes, but not in the case of hollow fiber membranes. The permeability of the hollow fiber membrane was higher when they were made of more hydrophobic polymers. The selectivity of the hollow fiber membrane was higher than that of the flat sheet membrane. When the membrane bioreactor was operated at a hydraulic retention time of 8 h, the recovery of the inlet wastewater was improved, probably as a result of the higher flux of the hollow fiber membranes.

The use of mobile communication systems is increasing steadily. As a result, the number of mobile communication devices has steadily increased, causing increased demands on the existing infrastructure and on the available resources. For example, many mobile communication devices have a cellular communication component that communicates with other communication devices and accesses a cellular network through a wireless communication device. The cellular communication component of the mobile communication device is typically located on a printed circuit board. The antenna of the cellular communication component is generally positioned on a
