Milk production and health of dairy cows under summer feeding conditions. Nine multiparous Holstein cows in midlactation were evaluated for their feed intake and subsequent milk production. Cows were fed to maximize production during a 50-d period. Ruminal pH, activity of lactate dehydrogenase in the ruminal fluid, and blood parameters of glucose, iron, and concentrations of milk and plasma ions were monitored during the 50-d period. Mean daily milk production was similar for the three treatments. Mean ruminal pH decreased during the summer months by a mean of .05 units. Acidosis was not always accompanied by decreased feed intake or milk production. Ruminal pH less than 6.0 was not accompanied by clinically depressed milk production in any of the three groups of cows. Mean ruminal fluid lactate dehydrogenase activity was similar for cows fed hay and concentrate diets (.0024-unit differences). These cows showed a mean daily milk production of 15.4 kg; production of cows fed hay was 11.9 kg, and cows fed concentrate diets produced 19.6 kg. Blood glucose levels were higher when cows were fed hay than when they were fed concentrate diets (147 versus 80 mg/100 ml). On the day after the peak of the photoperiod, serum iron concentrations were similar for all cows. However, a dramatic increase in blood hematocrit occurred during summer months. During summer months, milk fat content in cows fed concentrate diets was higher than that in cows fed hay diets. Summer feeding conditions affected milk components, but these effects were subtle.
